The underlying idea of world history is that the interaction among human societies ① resembles not the relationships among building blocks, but rather among bacteria. Building blocks can be stacked next to or on top of each other, but they rarely if ever ② affect their neighbors' shapes or composition. Bacteria, however, fundamentally shape each other as they interact. Because the membranes covering bacteria are full of pores, bacteria can exchange genetic information and can even fundamentally ③ alter each other's basic make-up when they touch. Similarly, human societies in contact affect each other's development. World historians, ④ rejecting this, seek to understand human history through studying both developments within societies and the way in which societies relate to each other. They look not only at the process of invention but also at the key role played by the ⑤ spreading of people, things, and ideas around the world.

* membrane 얇은 막, 막피

Spotlights can be more or less focused. When focused to their maximum extent, they illuminate a very small area with a very bright light. When de-focused, they illuminate a larger area, but the light is less ① intense. The same is true for attention. When we are relaxed, and not in the grip of any particular emotion, our mental spotlight is relatively ② unfocused, and more thoughts may drift through our awareness. When an emotion occurs, however, our mental spotlight suddenly ③ contracts, focusing on one small thought to the exclusion of all others. This thought is usually a representation of the external object that ④ stabilized the emotion. Love, for example, makes it hard to think of anything except the beloved. Emotions are often blamed for ⑤ distracting us, so it might seem strange to say that they help to focus our attention. However, emotions distract us from one thought only to make us pay attention to another.
