

7 다음 빈칸에 들어갈 말로 가장 적절한 것은?

In a classic series of experiments, rats were given various types of food and then exposed to radiation several hours later that made them sick. The rats learned to avoid the foods that were followed by illness on the basis of a single trial. By contrast, when they were exposed to avoidable light and sound signals followed by radiation-induced sickness, the rats did not learn to avoid these signals even on repeated trials, although they did learn very quickly to avoid such signals when they were paired with electric shocks. The results suggest that the rats behaved as though they assumed that if they became sick this must have been caused by _____, but that exposure to noises and lights were not the sorts of thing that could cause sickness.

- ① something they ate
- ② a pair of electric shocks
- ③ unavoidable exposure to radiation
- ④ repeating a series of trials and errors
- ⑤ exposing themselves to sound signals

When you see an apple, how do you know it has seeds inside? You've never seen this apple before, but you know about the seeds because you generalize from other apples to this apple; in other words, you put this object in the category *apple*. You can identify the class or category to which an object belongs, even if you've never seen that particular example of the object before. A category is a group of objects that have something in common (e.g., *dog* is a category) and an exemplar is an instance of a category (a particular dog is an exemplar of the category *dog*). Your experience allows you to generalize, that is, to apply information gathered from one exemplar to a different exemplar of the same category. In other words, things you know from your experience with dogs (it eats, it breathes, it could bite you but probably won't, it smells when wet)

_____.

- ① are merely subjective
- ② can be applied to any dog
- ③ cannot be exact exemplars
- ④ are different from time to time
- ⑤ give you a prejudice against dogs
