Many fruits, vegetables, and flowering trees depend on pollinators, such as honeybees, for their reproduction.

- (A) These include loss of habitat of the pollinators (for example, forests), invasive species of parasites (for example, fire ants that attack honeybee populations), viral infections transmitted from abroad, and large-scale use of pesticides, which kill the pollinators.
- (B) Indeed, the fruit industry spends vast sums of money on bee pollinators. There is now a mass decline in the wild populations of many pollinators, including honeybees, and also a replacement of native pollinators by unsuitable invasive species.
- (C) The results will be declining crop productivity and rising food costs. There is, as with the other areas of disastrous biodiversity decline, a multitude of interacting factors, probably all of which are contributing to the decline.

Our brain is a great computing machine, but it also places some obstacles in the way of apprehending reality truthfully.

There is no question that the brain-mind mechanism is one of the most glorious achievements of evolution. (①) Unfortunately, despite its many amazing features, it has also developed several procedures that are less desirable. (②) Every impressive evolutionary adaptation winds up blocking other possibilities: the bat has an exceptionally sensitive sonar but poor eyesight; the shark can't see well either but has a fantastic sense of smell. (③) The first of these is the nervous system itself. (④) The more that is known about how the mind works, the more we realize that the filter through which we experience the world has some peculiar built-in biases. (⑤) If we do not understand how these biases work, thoughts and actions are never truly going to be under conscious control.
