The biggest errors in judging a person are made by his parents; this is a fact, but how is one to explain it? We notice that travelers in a strange land grasp correctly the common, distinctive traits of a people only in the first period of their stay; the more they get to know a people, the more they forget how to see what is typical and distinctive about it. As soon as they see up close, they stop being farsighted. Might parents judge their children wrongly because they never stood far enough off from them? A quite different explanation would be the following: people tend to stop thinking about things that are closest to them, and simply accept them. When parents are required to judge their children, it is perhaps their _____ that makes them judge so mistakenly.

- ① false first impression
- ② habitual indecisiveness
- ③ overprotective tendency
- ④ natural lack of affection
- ⑤ customary thoughtlessness

Brain development is a fascinating construction tale, in which genes and environment collaborate to make us who we are. At some times during pregnancy, the fetus's brain makes 250,000 new nerve cells per minute. Babies are born with 100 billion neurons, but only a relatively small number of them are connected. In the first decade of life, a child's brain forms trillions of connections. New research has shown that early childhood experiences do not just create a background for development and learning, but they directly affect the way the brain is wired. In turn, the wiring profoundly affects our feelings, language, and thought. Experiences do not just influence a child's development; they finish the job of molding and sculpting the brain. About three-quarters of the brain develops outside the womb, in response to environment and experience. That is, _____.

- ① nature and nurture always work together
- ② sharing experiences leads to new insights
- ③ the body is the sacred temple of the spirit
- ④ the size of brain has to do with intelligence
- ⑤ the human brain is the most sensitive organ
