The longest war in human history is our ongoing war against insect pests. This war was declared about 10,000 years ago, when humans first got serious about agriculture. Today we are not much closer to winning this war than we were then. Some Chinese farmers recently decided to change strategies. Instead of spraying their rice and cotton fields with poisons, they build little straw huts around the fields in the fall. If this sounds crazy, it's crazy like a fox. These farmers are giving aid and comfort to insects' worst enemy, one that has hunted them for millions of years: spiders. The little huts are for hibernating spiders. Protected from the worst of the cold by the huts, far more of the hibernating spiders become active in the spring. Starving after their winter fast, they quickly rush into the fields to hunt their insect prey.

An alien species is any type of organism that is present in an ecosystem as a result of being introduced to that ecosystem through accidental or intentional means. Because they are not native to an area, alien species are sometimes referred to as exotic species, foreign species, or introduced species. Alien species are a matter of concern to environmental scientists because they often disrupt the natural balance of the ecosystem to which they are introduced. One example of an alien species is the zebra mussel. The zebra mussels inhabit the waters of the Great Lakes but are not native to the area. Scientists reported that zebra mussels were accidentally discharged from the ballasts of cargo ships from Asia that traveled to the ports on the Great Lakes. Over time, the zebra mussels have dramatically increased in population, threatening native mussels and clams by interfering with their reproduction, feeding, and movement.
